# **End to End Data Mining: The Next Challenge**

#### **Frans Coenen**

Department of Computer Science The University of Liverpool Liverpool L69 3BX

Tuesday 21 April 2009 ASC, Imperial

#### **Presentation Overview**

- Motivation ("Where I'm coming from").
- Some specific applications.
- A generic application (but with lots of different elements).
- Multi-Agent Data Mining (MADM), a potential solution.

### Motivation

#### Applied data mining.

- As a community we have produced a rich and successful range of data mining tools and techniques.
- However, many applications of our knowledge provide new and interesting challenges, often unique to the application under consideration.
- The main issue is the process of putting all the constituent parts together to address a given real world data mining task, i.e. the end to end data mining process.
- This presentation focuses on a number of sample real-world applications so as to highlight the challenge, and then presents a potential solution.

- (A particular problem example.)
- We wish to classify MRI scan data collections, for medical research purposes, according to a particular feature in these scans called the Corpus Callosum (CC)
- The conjecture is that the shape and size of the CC serves to distinguish, for example, musicians and non-musicians. It is also suspected that the shape and size of the CC plays a role in the identification of medical conditions such as epilepsy, schitsophrenia, autism, etc. The size and shape is also effected by age.

#### Example images:

Minimum Bounding Rectangle (MBR)

Tesselate

ID Colour Blocks

(4)

# AMD (<u>Age related Macular</u> <u>Degeneration</u>) Example (1)

- (Another specific problem example.)
- We wish to provide screening support for the early diagnosis of AMD.
- A common (standard) mechanism for doing this is by identifying "drusen" in retina scans.

## **AMD Example (2)**

- Histogram approach
- Histogram is in effect a time series.
- Consequently we can use time series analysis techniques, in this case dynamic time warping.

## AMD Example (3)

Dynamic Time Warping (DTW).

Case base of known time series which new case is compared to.

### **Trend Mining**

- (A more generic problem example.)
- Many institutions and commercial enterprises are interested in trends.
- The technique adopting (in various forms) is emerging and/or jumping pattern (EPs and JPs) mining.
- This is an extension of established Association Rule Mining (ARM) technology that looks at how the significance (support) of identified patterns (itemsets) changes over time.
- Number of collaborations in this area.

## **Trend Mining in Customer Bases**

- Particular case is in collaboration with a freight forwarder who wish to identify groups of customers (may be very small groups) whose behaviour changes.
- Patterns here are made of attributes from the customer base: location of sender, destination, weight, size, price, route, etc. Data all requires pre-processing.
- Once emerging/jumping patterns have been identified need to trace patterns back to customer IDs.

## **Trend Mining in Social Networks**

- Particular case is The UKs cattle movement DB.
- Large DB recording all cattle movements between locations in the UK (administered by DEFRA).
- Represents a time stamped social network (social network mining).
- Using the EP and JP idea to identify changes in behaviour.
- Aim is to determine the effect that changes in government policy and working practices might have (or not have).

# Trend Mining in Medical Applications

- Longitudinal data sets are common in medical applications (patient records).
- Work with diabetes unit at The Royal Liverpool Hospital.
- Royal Liverpool Hospital has the largest collection of diabetes data records in the UK (actually four DBs).
- Patients have regular consultations.
- Problems with: (a) missing data, (b) heterogeneity
- Interested in changes in patient data (but lack of change is also interesting).

# Trend Mining in Web Usage Mining

- Web usage mining is a popular KDD application.
- Learn Higher initiative.
- We wish to identify changes in WWW site usage behaviour.

- This is expected to provide information which will in turn provide evidence for restructuring of the site.
- Input is WWW log data time stamped at weekly intervals.

## Multi-Agent Data Mining (1)

- A potential generic solution is using a MAS (Multi-Agent System) approach.
- Vision is that of an anarchic collection of software agents; contributed by various participants, and cooperating to address a rich range of KDD tasks.
- The challenge is that the technical domain of KDD and (as already illustrated) the variety of applications is extensive.
- Propose EMADS, The Extendible Multi-Agent Data Mining System.

# Multi-Agent Data Mining (2)

## Multi-Agent Data Mining (3)

- EMADS supports extendibility through a number of predefine generic (Data and DM) wrappers.
- Wrappers are in effect EMADS agents in there own right that merge with whatever they are used to wrap to become data mining or data agents.
- Data mining wrappers require some programming knowledge.
- ➡ In case of Data wrappers, usage is facilitated by a GUI.
- (Creation of task agents requires more extensive knowledge, but not excessively so.)

#### Summary

Motivation ("Where I'm coming from").

- Some specific applications: MRI scan and Retina image mining.
- A generic application (but with lots of different elements): Freight forwarding, cattle movement social network, longitudinal patient data sets and WWW usage mining.
- A potential solution: Multi-Agent Data Mining (MADM).
